PS 1

Digital Estate & Financial Closure Assistant for Grieving Families

Problem Statement:

When someone dies, their family doesn't just grieve — they inherit a nightmare: forgotten insurance policies, unclaimed EPF/PPF accounts, active loan EMIs still getting deducted, subscriptions auto-renewing, and nominee details that are missing or outdated, with no single record of what the person even had. Banks, insurers and digital platforms all run separate, painful, paperwork-heavy death-claim processes. As a result, thousands of crores sit unclaimed in Indian financial institutions every year simply because families never find out an account existed.

Objective:

Develop a practical solution that helps bring clarity, organization, and timely action to the financial challenges described above.

- Improve clarity and organization around the financial responsibilities and information involved.
- Help users identify relevant concerns and make informed decisions about next steps.
- Create a practical solution that can support different circumstances and stages of the process.

ENIGMA 5.0 — GENESIS: BEYOND THE FUTURE

Federated Learning for Cross-Institution Financial Risk Control

Problem Statement:

Every bank, insurer and lending app holds a different slice of a customer's financial life — repayment history, claims patterns, spending behaviour — and none of them can pool it to build a sharper risk model, because moving raw customer data across institutions turns a modelling problem into a compliance one. Under data-protection regimes like India's DPDP Act or China's PIPL, centralising that data isn't just risky, it's often not allowed. So institutions default to training on their own thin, siloed data, which means weaker fraud detection, worse credit decisions for thin-file customers, and blind spots that only surface after a default or a loss.

Objective:

Develop a collaborative approach that addresses the financial risk and data-sharing challenge while preserving the underlying privacy requirements.

- Enable meaningful insights or decisions to be developed from information that remains distributed.
- Address the challenges associated with collaboration, privacy, and responsible data use.
- Demonstrate that the proposed approach is practical and effective in a relevant financial context.

Personalized Hidden-Ingredient & Dietary-Risk Alert System

Problem Statement:

Millions of people managing chronic conditions — diabetes, CKD, food allergies, PCOS, hypertension — are silently harmed by what they eat, not because they're careless, but because the danger is invisible. A 'sugar-free' biscuit can be loaded with maida and hidden syrups; a 'healthy' salad can carry a sodium load that spikes blood pressure; a common spice mix can contain an allergen never clearly listed. Doctors give a generic 'avoid oily and sugary food' instruction in a five-minute appointment, but nobody translates that into the dozens of real food decisions a patient makes every day at a store, a tiffin service, or a wedding buffet. Existing ingredient-scanning apps solve a lifestyle problem (vegan or not) — none solve a clinical one, where the wrong bite can trigger a hospital visit.

Objective:

Develop a personalized decision-support solution that helps people better understand food-related risks in their everyday situations.

- Help individuals make better-informed decisions about food in relation to their personal circumstances.
- Account for the complexity, variability, and limitations of information available in real-world situations.
- Present relevant information in a clear, understandable, and responsible manner.

Personalized Medication Management & Adherence

Problem Statement:

Misunderstanding prescriptions and complex medication regimens can lead to missed doses, incorrect medication usage, and poor treatment adherence. Patients often struggle to understand their prescriptions, manage multiple medicines, recognize potential medication-related risks, and stay consistent with their treatment plans.

Objective:

Develop an AI-powered platform for personalized medication management and adherence.

- Help users identify potential medication-related risks and receive timely support.
- Enable secure coordination between patients and their trusted caregivers.

Discovering Hidden Industrial Symbiosis

Problem Statement:

Industries generate large quantities of by-products and residual materials that are often treated as waste. At the same time, other industries may purchase virgin raw materials that could potentially be replaced by suitable industrial by-products. However, such opportunities are difficult to identify because they depend on material properties, quantity, location, timing, transportation, processing requirements and environmental impact.

Objective:

Develop a practical data-driven solution that helps uncover and assess opportunities for industrial resource exchange.

- Improve the identification of opportunities for better utilization of industrial resources.
- Consider relevant practical, operational, and environmental factors when assessing opportunities.
- Demonstrate how the proposed approach can be useful across different industrial contexts.

Smart Circular Economy & Waste Exchange Platform

Problem Statement:

Most 'circular economy' effort still collapses at the first bin: waste gets mixed at the source, sorting is manual and inconsistent, municipal bins overflow or sit half-empty with nobody tracking which, and material a neighbour would happily reuse just gets landfilled because no local channel exists to move it from the person who's done with it to the person who wants it. Cities can build all the downstream recycling capacity they want, but it doesn't matter if what arrives is already contaminated — and residents get no visibility into what happens after the bin, which kills any incentive to sort properly in the first place. The same pattern shows up globally: work on desertification, water efficiency and biodiversity protection — the kind featured in China's "Green Tech Innovation" track at the Bund Summit — keeps circling back to how well a community manages the resources already moving through it, not just the ones it extracts fresh.

Objective:

Develop a practical circular-economy solution that improves how communities identify, manage, reuse, and exchange materials.

- Improve how communities manage, reuse, and circulate materials.
- Explore practical ways to reduce waste and improve resource utilization.
- Demonstrate meaningful impact and the potential for application beyond a single local setting.
